

the Results of the Monitoring for Collecting Basic Data in Restricted Areas and Planned Evacuation Zones

July 1, 2011

Team in Charge of Assisting the Lives of Disaster Victims, Cabinet Office
Ministry of Education, Culture, Sports, Science and Technology

On June 13, the Team in Charge of Assisting the Lives of Disaster Victims, set up by the Cabinet Office, and the Ministry of Education, Culture, Sports, Science and Technology announced that they would conduct detailed air dose rate monitoring in restricted areas and planned evacuation zones (hereinafter referred to as the “target area”), as a part of the Enforced Plan on Environmental Monitoring (see the reference).

The Monitoring for Collecting Basic Data was conducted in two locations, i.e., near Namie station and Tomioka station, which are urban places in the target area and have various types of environment. The monitoring results are as follows.

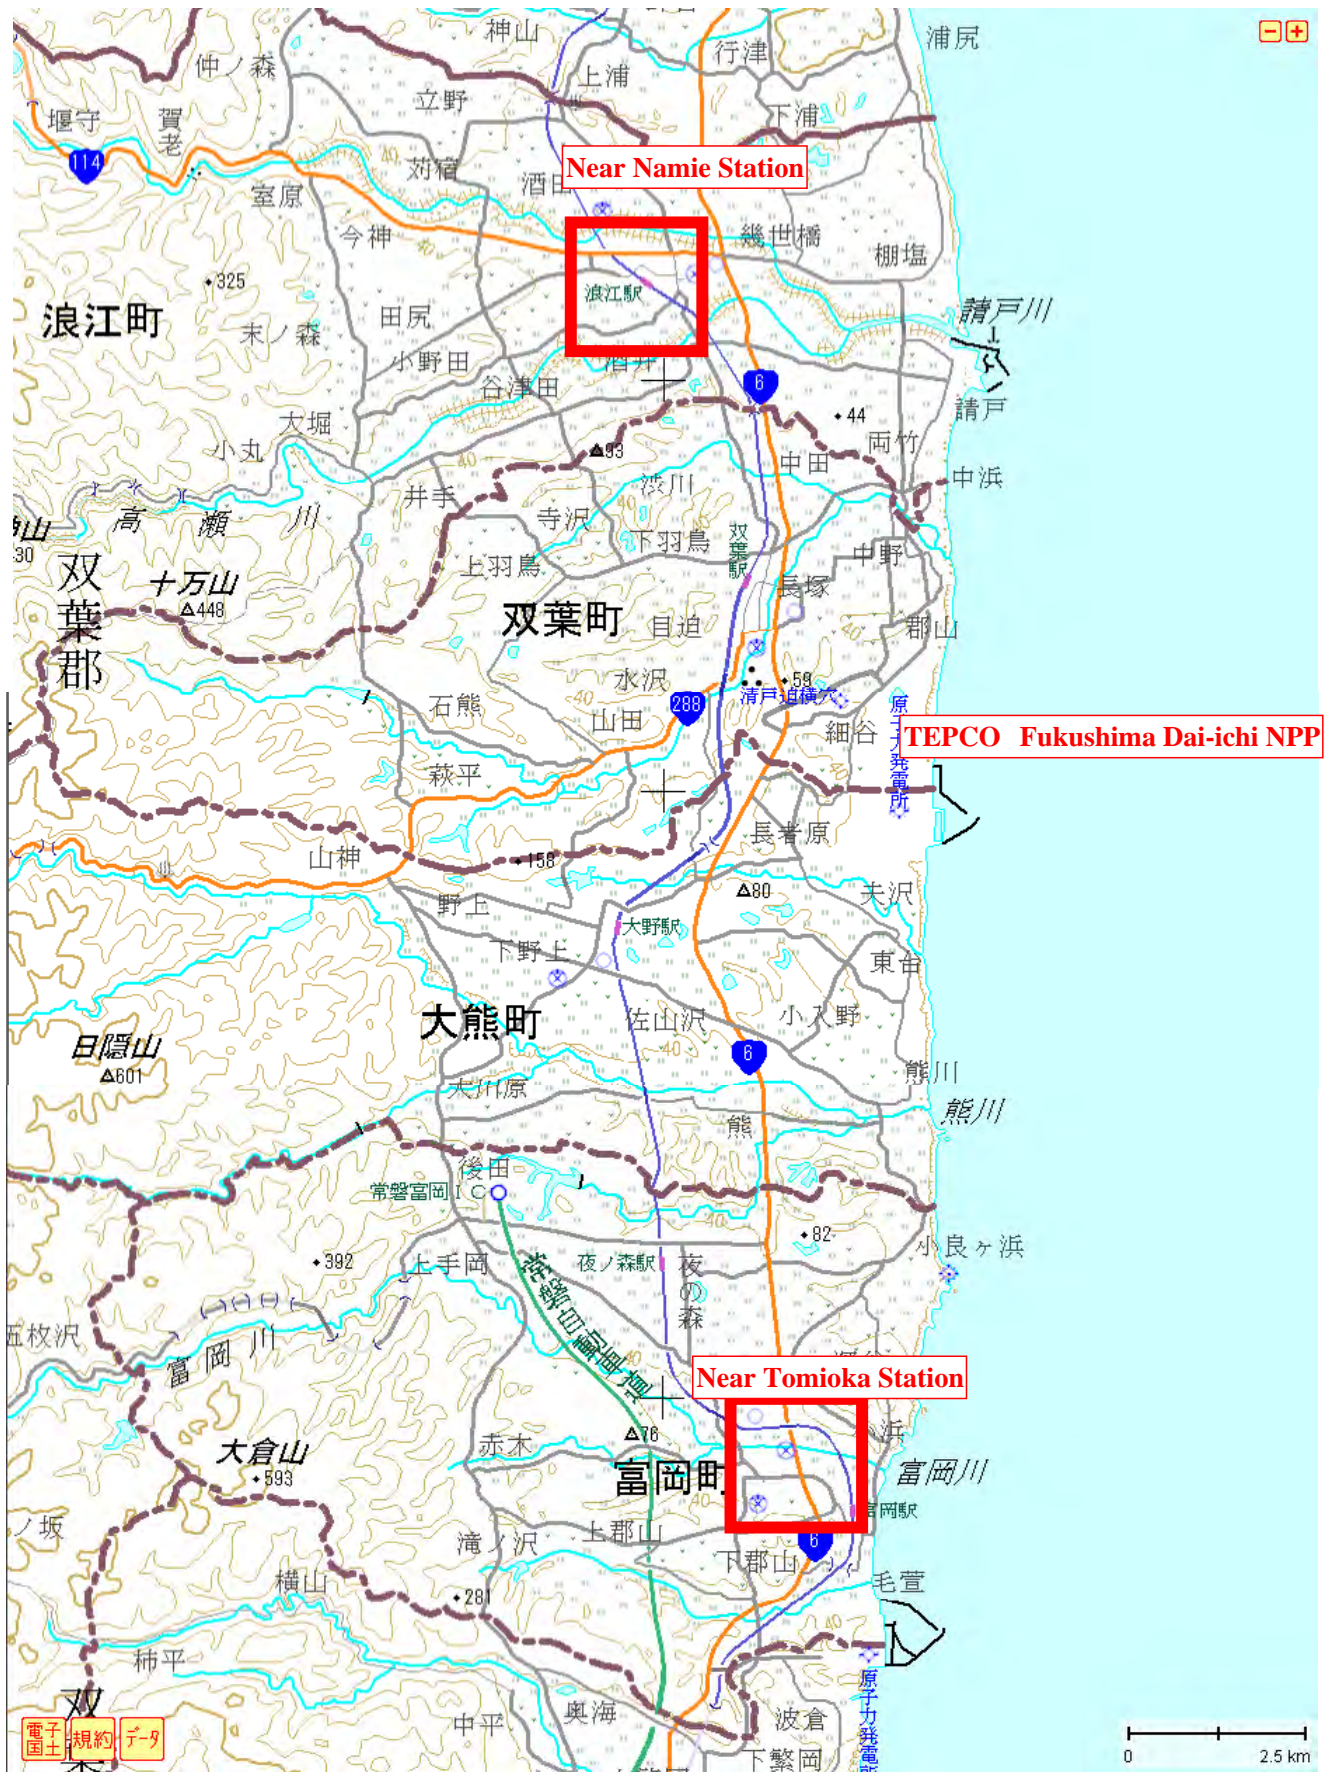

Based on these results, wide-area monitoring* is to be conducted in the target areas.

Outline of Monitoring for Collecting Basic Data

1. Period: June 13 to June 23, 2011
2. Locations: 2×2 km grids near Namie station and Tomioka station (Annex 1)
3. Monitoring points: Air dose rates at 1m and 1cm above the ground surface shall be measured at 400 points each at the above-mentioned two locations, by dividing the locations into 100×100 m grids
4. Monitoring results: The outline of the results is as shown in Annex 2.
Near Namie station: Annex 3-1 to 3-3
Near Tomioka station: Annex 4-1 to 4-3
5. Performed by: Central Research Institute of Electric Power Industry and TEPCO

* Based on the data obtained from the Monitoring for Collecting Basic Data, wide-area monitoring shall be conducted by first dividing the target area into 2×2 km grids (217 grids in total) and then selecting around 20 points per grid. This monitoring aims to ascertain the distribution of air dose rates (points showing especially high air dose rates) in various types of environment (such as different types of land usage within each grid).

Monitoring Locations (near Namie Station and Tomioka Station)

Results of the Monitoring for Collecting Basic Data (Results of the Monitoring near Namie Station and Tomioka Station)

Outline

Among the 2×2 km grids, air dose rates vary from about 1μSv/h to about 10μSv/h, which means the highest rate is more than ten times greater than the lowest rate. Some points showed anomalous values due to specific land use. However, the distribution of monitored air dose rates is considered to be caused by the concentration of radioactive substances that was discharged and accumulated in soil, etc. after the nuclear accident.

This result of the distribution of air dose rates agree well with the results of the airborne monitoring conducted by MEXT and the U.S. Department of Energy.

Insight obtained through the current monitoring

- Generally, in places where the ground surface is soil, air dose rates were higher for points closer to the ground surface, while in places widely paved with asphalt, such as roads and parking lots, air dose rates were relatively lower than those in surrounding areas. In the latter case, air dose rates measured 1cm above the ground were lower than those measured 1m above the ground. It can be presumed that the values were low at points close to the ground surface because radioactive substances on asphalt had been washed away by rain while air dose rates at 1m above the ground had been affected not only by the conditions of the ground surface but also by the surroundings, including nearby trees.
- At monitoring points under relatively large roofs, such as entrances to police stations and house carports, air dose rates were generally low. This may be because radioactive substances lay on the rooftop, instead of falling onto the ground surface.
- Air dose rates were high at the periphery of forests but were lower deep into forests. This may be because of the influence of radioactive substances, which lie and settle on tree leaves but do not fall onto the ground surface in the depths of forests, where leaves grow thick on top of each other. However, air dose rates were relatively higher at shrines and the like, which are surrounded by forests.
- Air dose rates were higher in grasslands, paddy fields, and upland fields. This may be because discharged radioactive substances adhered to plants and soil and have not been easily washed away by rain.

Policies for the future wide-area monitoring

Through planned wide-area monitoring, we will ascertain the trend of air dose rates at each location, while utilizing the abovementioned insight. Each of the 2×2 km grids shall be divided into 16 smaller grids (4×4) to conduct monitoring. Based on the abovementioned insight, some points may show anomalous values. If there are any such points, we will conduct measurement there as well.

Notes)

* Responsible entities are Central Research Institute of Electric Power Industry and TEPCO

* Measurement was not conducted when it was raining.

* Air dose rates are values measured by NaI (sodium iodide) scintillator detector. Only those marked with * (B13: 1cm above the ground) were measured in an ionization.

Notes)

* Responsible entities are Central Research Institute of Electric Power Industry and TEPCO

* Measurement was not conducted when it was raining.

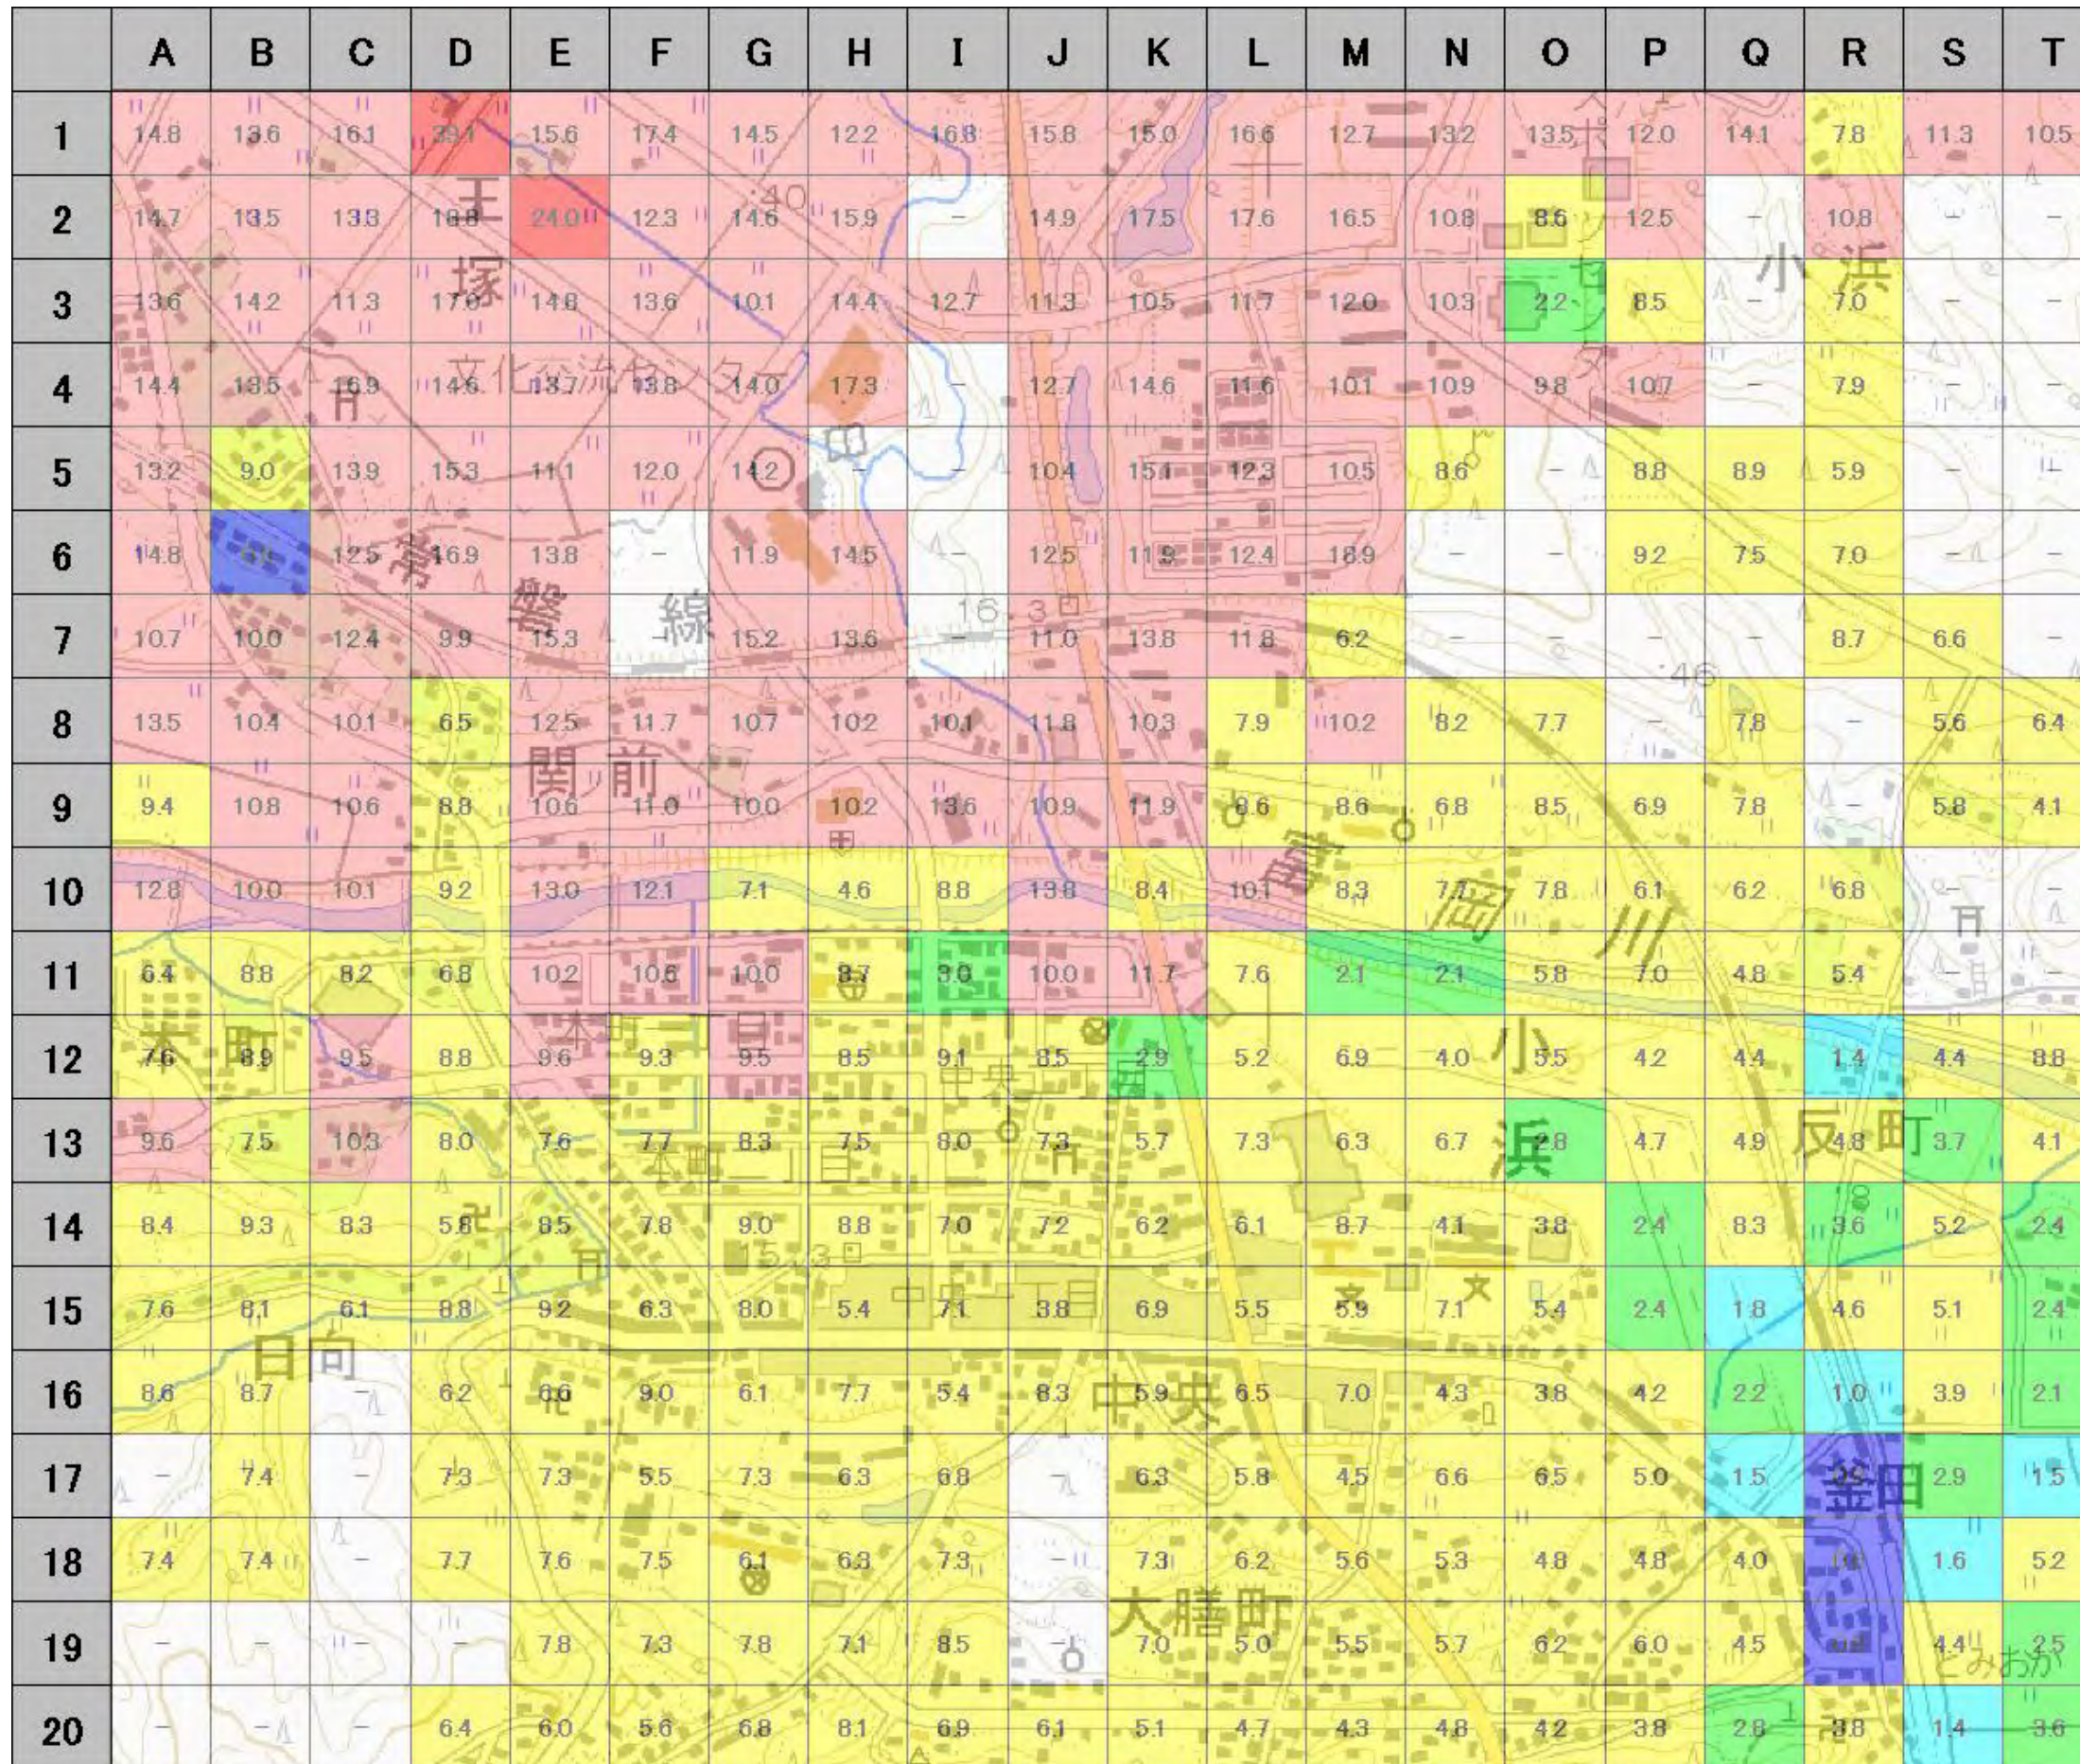

* Air dose rates are values measured by NaI (sodium iodide) scintillator detector. Only those marked with * (D1: 1cm above the ground) were measured in an ionization.
